(57) **ABSTRACT**

A method comprises determining (**101**) sensing input and determining (**103**) a likelihood that a human or animal is present based on the sensing input. The sensing input reflects changes in radio frequency signals received by one or more devices. The method further comprises controlling (**105**) a lighting device to render a light effect upon determining that the likelihood exceeds a presence detection threshold, and to continue to render the light effect for a subsequent predetermined period of time even when the likelihood changes by more than a predetermined value within the predetermined period. The method further comprises indicating (**107**) the likelihood to a user via an indication selected from a plurality of indications, e.g. by rendering the indication on the lighting device. A different indication of the plurality of indications is selected upon determining that the likelihood has changed more than the predetermined value.
