ABSTRACT

Methods, apparatus, systems, and articles of manufacture are disclosed. An example system includes interface circuitry; first programmable circuitry; and instructions to cause the first programmable circuitry to: determine, based on a first signal output by a first sensor, a first temperature at a first location that is associated with second programmable circuitry; determine, based on a second signal output by a second sensor, a second temperature at a second location that is different than the first location; set a first thermal setpoint for the second programmable circuitry in response to the second temperature failing to satisfy a threshold value; and set a second thermal setpoint for the second programmable circuitry in response to the second temperature satisfying the threshold value, wherein the second thermal setpoint is higher than the first thermal setpoint.
