ABSTRACT

A display device includes an image display unit, drive signal lines, and a drive. The image display unit includes pixel units and emission control signal lines that supply image signals to columns of pixel units of the pixel units. The drive signal lines supply image signals to the emission control signal lines. The drive is configured to supply an image signal to each drive signal line. The image display unit further includes switches each connected to the corresponding drive signal line. One normal drive signal line of the drive signal lines and at least one additional drive signal line are connected to the corresponding emission control signal line through the corresponding switch. Each switch is selectively settable at least to a first conductive state to allow an image signal to be provided from the drive to the corresponding emission control signal line through one normal drive signal line or a second conductive state to allow an image signal to be provided from the drive to the corresponding emission control signal line through at least one additional drive signal line.
